Hobart Closed Landfill 2010 Annual Groundwater Data Evaluation Report
Certification

I certify in accordance with the requirements of Chapter 18.220 RCW, that the contents of this Groundwater Data Evaluation Report were prepared under my direction under a system designed to assure that qualified personnel properly gathered and evaluated the information submitted. Where applicable, some specific and related hydrogeologic portions have been duly certified by the responsible geologist or engineering geologists in accordance with Chapter 18.220.010 (12) RCW. Based on my inquiry of the person(s) directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete.

EXECUTIVE SUMMARY

This annual report presents the Hobart Landfill evaluation of groundwater quality and water level data collected from October 1986 through September 2010.

Groundwater investigations in the mid 1980s led to remediation design and installation of a bentonite slurry wall to isolate the shallow groundwater beneath the refuse from the aquifer present below the landfill. The groundwater beneath the site was pumped out and a lower water level inside the slurry wall has been maintained since 1989. Final closure of the north half of the landfill was completed in 1990 and of the south half in 1994, with the placement of a High Density Polyethylene (HDPE) cap, drainage layer, and vegetative layer over the refuse.

Groundwater quality and water level data were collected and reviewed to summarize and evaluate groundwater quality at Hobart Landfill and determine changes, if any. Water quality data includes samples collected from nine monitoring wells.

Water quality data were entered into the King County environmental database to assist with data evaluation. Subsequent statistical analyses were performed on the data to generate and evaluate water quality trends in individual wells and to compare these trends between wells and hydrogeologic units. The influence of groundwater remediation, completed in April 1989 (slurry wall and water level drawdown), has been considered in this data evaluation.

Groundwater flow beneath the landfill has been evaluated by a licensed hydrogeologist. The report is included as Appendix B. The groundwater beneath the landfill occurs in two aquifers, the shallow aquifer and the deep aquifer. In both zones, the water generally flows in a southwesterly direction.

During the current evaluation period, water quality continued to demonstrate the improvements that have been apparent since remediation and closure. The demonstrated quality improvements together with the maintained head differential across the slurry wall provide indications that the slurry wall is continuing to function as designed. Monitoring at the landfill will continue throughout the required post closure period. In general, water quality in both aquifers has improved over time and demonstrates stability in current conditions.

Engineered controls at the landfill will continue to be maintained. These controls include the cover system, a landfill gas collection system, and a leachate extraction system. The water levels inside and outside the slurry wall are monitored monthly to determine whether there is at least 10 feet of separation. The leachate extraction system will be reactivated if water levels rise above 620 feet, so as to maintain vertical separation between the aquifer and the base of waste.

CHAPTER 1

1.1. OBJECTIVES

The objectives of the Hobart Landfill groundwater quality evaluation are as follows:

- Assemble groundwater quality data from September 1986 through September 2010.
- Review data and perform statistical analyses to evaluate any water quality trends, and to compare water quality between monitoring wells.
- Compare water quality data with water quality standards in effect at the time of sampling. Document any exceedances of water quality standards.
- Determine whether impacts to groundwater quality recorded in monitoring wells can be attributed to the landfill.

1.2. SITE SUMMARY

Hobart Landfill is located on 276th Street Southeast, between the towns of Hobart and Ravensdale, about 25 miles southeast of Seattle (Figure 1). The landfill is owned by King County and was operated and is maintained by the King County Solid Waste Division (KCSWD). It occupies approximately 75 acres, of which about 35 acres have been used for refuse disposal.

Prior to the early 1950s, the Hobart Landfill site was utilized as a sand and gravel pit. Landfill activities began in the 1950s, with refuse being placed in the former sand and gravel pit. Open burning of refuse occurred until the early 1960s. From the early 1960s to 1990, refuse was placed in a controlled manner, including compaction and later placement of a daily cover.

A site characterization investigation in August 1983 included construction and sampling of four groundwater monitoring wells and characterization of surficial soils. Expanded site characterization investigations were performed between August 1985 and March 1986 and consisted of additional three wells installed in solid waste, and 22 wells installed in native soils surrounding the landfill. Quarterly groundwater monitoring is currently performed in nine wells, of which six are in the Shallow Aquifer and three are in the Deep Aquifer (Table 1.1). The landfill site map (Figure 2) shows the monitoring well locations.

Water quality impacts to the Shallow Aquifer were detected on site, triggering remedial activities in the Shallow Aquifer. Site remediation occurred during 1988 and 1989, including

construction of a low permeability soil and bentonite slurry cutoff wall around the landfill. Site remediation is further described in Section 1.2.2.

In 1990, an HDPE final cover with a gas collection system was installed over 14 acres of the solid waste at the northern half of the fill (Phase 1 closure).

In 1994, the remaining southern portion of the landfill was closed under the Phase 2 closure project. This included: construction of a final cover and landfill gas collection field over the south half of the landfill, modifications and repairs to the existing landfill gas flare system and utilization of existing infiltration basins for stormwater runoff.

1.2.1. GEOLOGY AND HYDROGEOLOGY

Hobart Landfill site characterization, including history, hydrogeology, and details regarding the slurry cutoff wall, has been documented in the reports listed in References. This section presents a summary.

The Hobart Landfill is located within the Puget Sound lowlands of western Washington. Geologic studies at the Hobart Landfill have identified four lithologic units at the site. These units are recessional outwash, glacial till, advance outwash, and older undifferentiated deposits (OUD). Figure 3 (Harding, 1992) is a north-south cross section depicting the occurrence and variations in thickness of these units at the landfill.

Two groundwater systems have been identified beneath the site: a local or Shallow Aquifer in the recessional and advance outwash deposits, and a regional or Deep Aquifer in the pre-Vashon deposits. Beneficial use of groundwater in the vicinity of the landfill is limited to domestic wells withdrawing from the deep aquifer.

Shallow Aquifer: The Shallow Aquifer occurs continuously below the landfill site in recessional and advance outwash deposits. The aquifer is perched and unconfined, ranges from 5 to 36 feet below ground surface and is between 35 and 50 feet thick. The perching layer is the highly oxidized, low hydraulic conductivity, upper surface of the OUD. Below the highly oxidized upper surface of the OUD, unsaturated conditions occur for over 70 feet before the Deep Aquifer is encountered. There are currently 12 monitoring wells installed in the Shallow Aquifer, of which six are monitored on a quarterly basis. The six wells were selected for representativeness and location. Two additional wells are used to measure water levels only.

Deep Aquifer: The Deep Aquifer occurs between 130 and 150 feet below ground surface (average groundwater elevation of 510-feet msl). The aquifer occurs in the pre-Vashon sand and gravel deposits and appears to be unconfined. There are currently three monitoring wells installed in the Deep Aquifer, one up-gradient (MW-25), and two down-gradient (MW-3 and MW-7). MW-9 was decommissioned in 2001 after it was damaged in the Nisqually earthquake. MW-25 was installed at that time to provide upgradient monitoring. The Deep Aquifer is believed to discharge to the Cedar River located southwest of the site.

1.2.2. SITE REMEDIATION

A low permeability bentonite slurry wall was installed in 1989 around the refuse and keyed into the Shallow Aquifer perching unit. Three extraction wells were installed in the Shallow Aquifer beneath the refuse. Groundwater extraction commenced from the Shallow Aquifer within the slurry wall to reduce hydraulic heads 10 to 20 feet below those immediately outside of the slurry wall and maintain an inward hydraulic gradient. This maintains the water table surface below the level of deposited waste and maintains an inward hydraulic gradient around the site minimizing the potential for migration of contaminants.

The Walsh Lake Diversion Ditch, flowing upgradient of the landfill, was lined in selected areas around the same time that the slurry wall was constructed to reduce Shallow Aquifer recharge and thereby reduce hydraulic head in the vicinity of the solid waste.

After the 1994 final closure, the infiltration through refuse has been sufficiently reduced such that extraction is no longer necessary. The water levels on the interior of the slurry wall are monitored monthly together with four selected monitoring wells outside of the slurry wall. A comparison of these water levels monthly provides verification that water levels inside the slurry wall remain well below outside levels, insuring that the slurry wall and impermeable cap are functioning properly.

In 2009, AMEC Geomatrix evaluated the conditions and effectiveness of the slurry wall and groundwater control system. It was determined that the piezomoters and monitoring well network provides sufficient and valid water level information. Should water elevations within the slurry wall rise, pumping capacity is adequate to counter a 0.5 ft/year rise thus maintaining hydraulic head differences and inward gradients verifying continued effectiveness of the system.

Figure 4 shows the historical levels of hydraulic head in monitoring wells located outside the slurry wall and water level measurements obtained inside the slurry wall.

This page is left blank intentionally

CHAPTER 2

DATA EVALUATION

2.1 GROUNDWATER ELEVATIONS AND FLOW DIRECTION

Groundwater levels in individual wells have been plotted as a function of time (Figures 5 & 6). Groundwater flow directions were estimated based on water elevations recorded in monitoring wells screened in similar water-bearing zones (Appendix B). Upgradient and downgradient wells are determined by flow direction.

Shallow Aquifer: Piezometric flow maps, based on water levels recorded in the on-site monitoring wells, indicate a general aquifer flow to the southwest (Appendix B). The slurry wall is constructed of low permeability materials that prevent inward flow. The measured water levels for wells outside the slurry wall and piezometers inside the slurry wall are shown in Figure 4. Seasonal variation of up to eight feet in water level measurements has been observed for individual wells (Figure 5).

Deep Aquifer: Piezometric surface maps (Appendix B) based on the three monitoring wells indicate a westerly to southwesterly hydraulic flow direction depending on the season. A seasonal water level fluctuation up to 6 feet has been recorded in the three on-site monitoring wells. Water level fluctuation in these wells has lagged behind that of the shallow wells by about one month (Figure 6).

2.2 DATA EVALUATION METHODS

The King County Solid Waste Division (KCSWD) assembled the analyte list from parameters listed in WAC 173-200 Ground Water Criteria, WAC 173-351-990 Appendices I and II and 40 CFR 141 and 143, National Primary and Secondary Drinking Water Standards. Some of these analytes are useful in characterizing groundwater quality, as indicators of impacts to groundwater from landfill gas and leachate, or in screening for potentially harmful effects to human health and the environment. It is these analytes that the data evaluation focuses on.

Environmental samples are collected, analyzed and evaluated by the procedures described in the Environmental Monitoring Quality Assurance Project Plan and Sampling Analysis Plan for Cedar Falls, Enumclaw and Hobart Closed Landfills (QAPP/SAP). The QAPP/SAP describes activities undertaken to ensure analytical results meet data quality objectives and that they are representative of actual groundwater conditions. For this report, the graphical representation includes those parameters that have exceeded regulatory limits or/and have a visual trend. The water quality discussion is focused on exceedances, trend table, graphs, and potentiometric maps.

2.3 GROUNDWATER CHEMISTRY RESULTS

This section presents results and interpretation of water chemistry evaluations performed for each groundwater monitoring well at the Hobart Landfill. The results are presented according to aquifer and location relative to the principal groundwater flow direction. Discussion emphasis is on results obtained since the last annual groundwater evaluation report, which covered samples through mid-2009. Statistical comparisons have been compiled for three time periods: prior to slurry wall construction (October 1986 to April 1989), post slurry wall construction (April 1989 to early, 2008), and the current reporting period (mid 2008 to mid 2010).

Exceedances of primary and secondary drinking water standards (DWS) as well as exceedances of water quality criteria (WQC), which have occurred during this reporting period (the last eight samples), are listed in Table 2-1. Descriptive Statistical and Trend Tables of field and analytical data are presented in Appendix C for the shallow and deep aquifer. Graphical representations of parameters with exceedances and/or visual trends are presented in Appendices D and E. Raw data are contained in Appendix F.

The results are used collectively to indicate the possibility of groundwater contamination. Corroboration by several indicators is necessary before impacts from landfill operations can be considered a reasonable conclusion.

2.3.1 SHALLOW AQUIFER MONITORING WELL RESULTS

Quarterly groundwater monitoring has been performed by KCSWD in six wells since 1986. Field and laboratory analysis results are discussed in this section. Wells are located north, south, and west of the landfill (Figure 2).

MW-11

MW-11 is located near the northeast corner of the site. It is also located near the Walsh Lake Diversion ditch, which may be a source of recharge to the Shallow Aquifer. This well serves as an upgradient monitoring well for the shallow water bearing zone (see Figure 2).

Data collected from MW-11 indicate that slightly acidic conditions prevail with consistent exceedances of the field pH lower standard limit. Specific conductance, total dissolved solids, alkalinity, chloride, sulfate, nitrate, ammonia, iron, and manganese are low and relatively stable. There are no short term trends in any monitored parameters.

Acetone was detected in MW-11 in September 2009. Acetone is a common laboratory contaminant. MW-11 also had 3 chloromethane detections. Chloromethane was also detected in one associated method blank. King County Environmental Laboratory has made the

following statement about the chloromethane detections in a letter on April 5, 2010.

"Low-level chloromethane detections identified by the lab could be related to the manufacture of the septa in the VOA vial caps, or a possible contaminant related to the acid preservative, or could be the by-product of a reaction between the HCl and a constituent in the sample itself."

For simplicity, future references to chloromethane contamination are described as artifacts of sample preservation.

Showing no signs of impacts, MW-11 is a good representation of ambient groundwater quality upgradient of the landfill and is an adequate upgradient monitoring well.

MW-1, MW-4, MW-6, MW-10, & MW-18

MW-6 is located in the southeast corner of the site and is located side gradient to the landfill. MW-1 is located near the southern boundary of the site. MW-10 is located southwest of the landfill while MW-18 and MW-4 are located west (see Figure 2). Piezometric head data indicate these last four wells are hydraulically downgradient of the landfill.

The water in these five wells tends to be slightly acidic to neutral. Chloride concentrations have decreased and stabilized at levels similar to upgradient conditions. Most of the wells exhibit long term decreasing trends for specific conductance, alkalinity, sulfate, iron, manganese, calcium, magnesium, potassium and sodium. With the exception of MW-4, nitrate is lower in concentration and detection frequency in these wells compared to conditions in MW-11.

In general, water samples from MW-1, MW-6 and MW-10 have relatively higher levels of specific conductance, total dissolved solids, alkalinity, calcium, iron, and manganese than upgradient groundwater. However, most of these parameters have long term decreasing trends. MW-6 has a statistically significant short term decreasing trend for specific conductance and manganese. MW-10 has a statistically significant short term decreasing trend for ammonia, nitrate, sodium, and manganese. MW-18 has a statistically significant increasing short term trend for calcium and sodium, and a decreasing trend for manganese. No other short term trends are evident in the current sampling period.

MW-4 and MW-18 parameter concentrations have declined and stabilized at levels similar to those upgradient for most parameters. The water quality conditions found in MW-4 are very similar to those at MW-11 and indicate no remaining impacts from landfilling activities.

No volatile organic compounds were detected in shallow wells except for acetone and chloromethane. Both of these contaminants were also detected in the background well, MW-11. They are not considered indicative of groundwater quality, as acetone is a common laboratory contaminant, and chloromethane is an artifact of sample preservation.

Secondary Drinking Water Standards (DWS) are exceeded for field pH in all wells. Arsenic exceeded Washington State Ground Water Quality Criteria (WQC) in all MW-10 samples. Iron exceeded secondary DWS in one of four MW-1 samples and all MW-10 samples. Manganese exceeded secondary DWS in all samples from MW-10 and MW-18, and three out of four samples for MW-1. No other DWS and WQC are exceeded during this period.

2.3.2 DEEP AQUIFER MONITORING WELL RESULTS

Quarterly groundwater monitoring has been performed by KCSWD in three wells since 1986. Field and laboratory analysis results are discussed in this section. Wells are located north, south, and west of the landfill (Figure 2).

MW-25

MW-25 is located north and, based on piezometric head data, is hydraulically upgradient of the landfill. This well was installed in 2001 to replace MW-9, which was damaged in the Nisqually earthquake.

Water in MW-25 is slightly alkaline. Specific conductance, alkalinity, chloride, sulfate, and iron levels are low and stable. Nitrate shows a statistically significant short term decreasing trend. There are no other short term trends for MW-25. Nitrate is regularly detected in MW-25, and shows no long-term trend. Arsenic is also regularly detected in MW-25 and is stable, showing no short term or long term trends.

Arsenic has exceeded the Washington State Water Quality Criteria (WQC) in all recent samples. No other DWS or WQC are exceeded.

Chloromethane was detected in two out of four samples during this reporting period. Chloromethane was also detected in the background well and is an artifact of sample preservation. It is not considered representative of groundwater quality. Dichlorodifluoromethane was detected in 3 out of 4 samples in MW-25 at concentrations greater than the method detection limit but less than the reporting detection limit.

The conditions found in MW-25 are considered representative of background water quality in the deep water bearing.

MW-7 & MW-3

MW-7 is located south and MW-3 is located west of the landfill. Based on piezometric head data these two wells are hydraulically down gradient of the site.

Water in MW-7 and MW-3 is slightly alkaline. Specific conductance, total dissolved solids, alkalinity, chloride, sulfate, calcium, magnesium, potassium, sodium and iron levels in MW-7 are higher than those in upgradient well MW-25. However, most of these parameters have significant long term decreasing trends in MW-7, except for ammonia which has long-term significant increasing trends. There were short-term increasing trends in MW-7 for calcium. In MW-3, significant increasing long term trends are detected for specific conductance, chloride, calcium, potassium, iron, and manganese. Increasing short term trends are also present for calcium and manganese, while decreasing short term trends are present for nitrate and alkalinity. Concentrations of these parameters remain relatively low, much closer to

upgradient (MW-25) levels than to downgradient well MW-7. Appropriate monitoring will continue in MW-3.

Arsenic is undetected for this period in both wells.

Acetone and chloromethane were detected in both MW-3 and MW-7. Acetone is considered to be a laboratory contaminant and chloromethane is considered to be an artifact of sample preservation. Dichlorodifluoromethane was detected in two out of four samples from MW-3 at concentrations above the method detection limit but below the reporting limit. No other volatile organic compounds were detected.

2.3.3 SHALLOW AQUIFER REMEDIATION

The slurry wall containment isolates the Shallow Aquifer beneath the landfill from the local groundwater flow system. Pumping wells installed beneath the solid waste and inside the slurry wall have lowered the groundwater table below the base of refuse. The water elevation outside of the slurry wall has remained consistently above the water elevation inside (See Figure 4). As a result, an inward hydraulic gradient has been created resulting in a system which reduces the possibility of breakthrough of contaminants and off-site transport.

Concurrent with the construction of the slurry wall, the northern half of the landfill was closed with an HDPE final cover. The southern half was later closed in 1994. Consequently, local recharge to the aquifer has been reduced.

Six indicators have been used to evaluate the site remediation: chloride, arsenic, manganese, cis-1,2-Dichloroethene, 1,1-Dichloroethane, and 1,1,1-Trichloroethane. Chloride is an early indicator of leachate, and manganese is sensitive to redox conditions. Their movement through groundwater is controlled by different chemical processes. Chloride migration is not retarded by such processes as adsorption, cation exchange, biological uptake or redox processes. The distribution of manganese, however, is strongly controlled by redox processes. Reducing conditions permit manganese to dissolve and be transported in groundwater. Reducing conditions prevail when oxygen is depleted by waste degradation and sustained by the presence of BOD and anaerobic metabolism. Thus, manganese may be an indicator of landfill impacts.

Chloride in all of the down and side gradient wells has been reduced to levels found in MW-11. Manganese levels have been reduced in all wells, but remain elevated relative to MW-11 in MW-1, MW-10 and MW-18.

Arsenic has been detected in one well in the shallow aquifer this period. The median concentration is 0.006 mg/L in MW-10, which is within the general range expected in this geologic area and is below the MCL of 0.010 mg/L.

Organic compounds have been detected with relatively low frequency and at low level both prior to and since construction of the slurry wall. The concentration levels for cis-1,2-dichloroethene, 1,1-dichloroethane, and 1,1,1-trichloroethane have been used to evaluate the success of remediation indicated by their decrease over time. There were no detections of these compounds in any of our wells during this reporting period.

A summary of the performance of the slurry wall and drawdown wells showing water quality prior to remediation and after remediation are presented in Table 2-2.

This water quality evaluation in conjunction with water level data shown in the potentiometric mapping and the trend analyses demonstrates that the slurry wall is functioning as designed. It is maintaining groundwater elevation separation below the waste and preventing groundwater migration within the wall perimeter.

CHAPTER 3

SUMMARY AND CONCLUSIONS

The conclusions of this groundwater data evaluation are presented according to aquifer and time period.

3.1 SHALLOW AQUIFER

The shallow perched aquifer is an unconfined water table aquifer that has historically saturated lower portions of the solid waste beneath certain areas of the site. Since completion of the Shallow Aquifer remediation in 1989, the shallow water table no longer comes into contact with solid waste, and the groundwater gradient around the site has been altered to minimize off-site transport from beneath the landfill.

Information presented in this report suggests that on-site monitoring wells installed in the Shallow Aquifer and located hydraulically downgradient of the landfill may have historically been influenced by landfill activities. When monitoring began in 1986, the downgradient wells had elevated levels of some leachate indicator constituents with respect to the upgradient wells. Since 1986, these constituents have become progressively less concentrated in downgradient wells, as a result of improved landfill site conditions and Shallow Aquifer remediation activities, particularly installation of the low permeability bentonite slurry wall.

Wells in the shallow water-bearing zone displaying impacts from landfilling activities consisted of MW-1, MW-10, MW-6, and to a lesser extent, MW-18 and MW-4. These wells are located along the west and south perimeter of the fill. Concentrations were greatest prior to completion of the slurry wall. Trend analyses show that statistically significant decreases in long term trends of indicator parameters have occurred in the side and down gradient wells. In general, water quality in this aquifer has improved and demonstrates stability in current conditions.

Volatile organic compounds associated with shallow aquifer impact prior to and in the early remediation phase have decreased and been detected infrequently since September of 2004. Reductions in the laboratory detection limits have confirmed concentrations have declined and are detectable only infrequently.

Current water quality conditions in the Shallow Aquifer continue to approach background and future increases in contaminant levels appear to be unlikely with the current site control.

3.2 DEEP AQUIFER

The refuse is located in excess of 100 feet above the deeper water bearing zone separated by about 80 feet of dry or moist soils. A low permeability (10^{-6} cm/sec) perching layer of the older undifferentiated deposits (OUD) is continuous beneath the site and separates the two hydrogeologic systems. The lack of moisture in the soils indicates that hydraulic connection between the fill and the groundwater is not strong and the soil capacity to retard contaminants is enhanced because it is not saturated.

General geochemistry parameters at MW-7 are elevated relative to the upgradient well, but all have shown decreasing trends over the short term (mid 2008 - mid 2010) except for calcium. Calcium shows an increasing short term trend, although the overall long term trend is decreasing. The concentrations of these parameters are below primary standards. Frequency of volatile detections in the deep aquifer has decreased considerably and the levels are close to detection limits.

The groundwater quality in the deep aquifer has improved over time.

3.3 RECOMMENDATIONS

Recommendations for the Hobart landfill are:

- Continue the maintenance of engineered controls.
- Continue monitoring water level and field parameters on a quarterly basis at all wells in the current monitoring network.

Due to continuing stability in the groundwater at this facility, the following two actions are also recommended:

- Change reporting to:
  a) Annually, a brief update of any major changes from previous year (one or two pages) attached with laboratory result data and field data.
  b) Quarterly, review and evaluation of monitoring data with notification to regulatory agencies only in the event of unusual occurrences or new primary standard exceedance.
- Continue monitoring quarterly field parameters.
- Adjust water quality sampling to a schedule based on groundwater velocities and modify parameter lists to focus on known concerns while maintaining overall water quality characterization.

The Solid Waste Division plans to discuss the recommendations on sampling and reporting frequency with the pertinent regulatory agencies.

Re: Contract Number: E00065E07 H
Potentiometric Groundwater Surface Mapping and Groundwater Velocity Calculation
Data Collected During the 2010 Water Year
Hobart Landfill
King County, Washington
Project No. 070074-007-01

Dear Mr. Jimenez:

This letter report presents an analysis of groundwater flow direction and rate during 2010 for the shallow and deep aquifers beneath the Hobart Landfill (landfill), in accordance with King County Department of Natural Resources, Solid Waste Division (KCSWD) Contract Number E00065E07 H. KCSWD personnel measured groundwater elevations in monitoring wells installed at the landfill quarterly during 2010. Groundwater level measurements representing the 2010 water year seasonal high and low water levels were received by Aspect Consulting on October 4, 2010 and were used to:

1. Evaluate the potentiometric groundwater surface elevation during the seasonally high and low water levels for the shallow and deep aquifers;
2. Determine the groundwater flow direction and horizontal gradient during the seasonally high and low water levels for the shallow and deep aquifers; and
3. Calculate the groundwater flow velocities during the seasonally high and low water levels in the shallow and deep aquifers.

No major changes in groundwater flow direction or velocity were observed for the deep aquifer since the previous report submitted for 2009 monitoring events.

No major changes in groundwater flow direction or velocity were observed for the shallow aquifer during high groundwater levels in 2010 since the previous report submitted for 2009 monitoring events. During low groundwater levels in 2010, groundwater flow was generally west, whereas in 2009 groundwater flow was to the north.

Groundwater Elevation Data

KCSWD measured groundwater levels quarterly during the 2010 at 11 on-site monitoring wells completed in the shallow or deep aquifers. Groundwater levels were also measured at five wells located inside the slurry wall which surrounds the landfill. Table 1 lists the well names, locations, reference point elevations, measured groundwater levels, and reported groundwater elevations for the shallow and deep aquifers, as well as for the water-bearing zone inside the slurry wall. High groundwater elevations were measured during the 1st quarter 2010 monitoring event performed between February 25 and March 3, 2010. Low groundwater elevations were measured during the 3rd quarter 2010 monitoring event performed August 20-23, 2010.

Figures 1 and 2 show well locations, groundwater elevations, inferred groundwater potentiometric surface contours, and inferred local groundwater flow directions in the shallow aquifer for high and low groundwater levels, respectively.

Figures 3 and 4 show well locations, groundwater elevations, groundwater potentiometric surface contours, and interpreted regional groundwater flow directions in the deep aquifer for high and low groundwater levels, respectively.

Direction of Groundwater Flow

Groundwater elevations from measurements made during high and low groundwater levels in 2010 indicate that groundwater in the shallow aquifer flowed generally west around the slurry wall. During both high and low groundwater levels, groundwater elevations at MW-16 were substantially higher than elevations observed at other shallow aquifer wells, and may indicate groundwater mounding upgradient of the landfill. It is inferred that as groundwater approaches the relatively impermeable slurry wall, it mounds near MW-16 and flows laterally around the north and south sides of the slurry wall. During 2010, water levels measured inside the slurry wall ranged from approximately 7 to 18 feet below groundwater levels outside the wall, indicating good hydraulic separation from the shallow aquifer.

Groundwater elevations from measurements made during the 2010 water year indicate that groundwater in the deep aquifers generally flowed west under both high and low groundwater level conditions.

Groundwater Velocity

Horizontal groundwater velocity was calculated using the following formula:

$$v = \frac{1}{n_{eff}} K \frac{\Delta H}{\Delta L}$$

where:
v = Groundwater velocity [L/t]
K = Hydraulic conductivity [L/t]
$\Delta H/\Delta L$ = Hydraulic gradient [L/L]
n_{eff} = Effective porosity [dimensionless]

Horizontal groundwater velocity was calculated for the shallow aquifer outside the slurry wall and for the deep aquifers below the landfill. Table 2 presents a summary of the hydraulic parameters that were used to calculate groundwater velocities for both aquifers during the seasonal high and low groundwater level conditions.

The shallow aquifer hydraulic conductivity was provided in the annual report for measurements made in 2002 (HWA GeoSciences Inc., 2003). The deep aquifer hydraulic conductivity of 7×10^{-5} centimeters per second (cm/sec) or 0.2 feet per day (ft/day) was calculated from a single well pumping test conducted at MW-3 as reported in R.W. Beck and Associates, and Sweet, Edwards & Associates (1984). This value is in the middle of the range of permeability reported for pre-Vashon deposits of 10^{-7} to 10^{-3} cm/sec (Galster and Laprade, 1991).

The hydraulic gradient in the shallow aquifer was determined from groundwater elevations measured in wells completed along the north, west, and south sides of the slurry wall. The gradient in the deep aquifer was determined from three wells, and did not change between high and low groundwater levels.

The velocity calculated in the shallow aquifer was approximately 4.4 ft/day during the high groundwater monitoring event in 1st Quarter 2010, and 4.0 ft/day, during the low groundwater monitoring event in 3rd Quarter 2010. The velocity calculated in the deep aquifer was approximately 0.03 ft/day, during high and low groundwater level conditions in the 2010 water year.

Notes:

1. Water level measurements made during 2010 water year by KCSWD personnel.
2. Coordinates are in feet based on Washington State Plane grid system.
3. Elevations in feet above mean sea level (ft MSL) based on the National Geodetic Vertical Datum, 1929.
4. High groundwater levels were measured between February 25 and March 3, 2010.
5. Low groundwater levels were measured August 20, 2010. Groundwater levels inside the slurry wall were measured August 23, 2010.
6. Coordinates at MW-25 and all locations inside the slurry wall were estimated from maps.

Hobart Closed Landfill Groundwater Monitoring Data

Hobart Closed Landfill Groundwater Monitoring Data

The Hobart Closed Landfill Groundwater Monitoring Data are available as Portable Document Format (PDF) files. To view PDF files you must have Adobe® Acrobat® Reader® software. With the Adobe® Acrobat® Reader® software**,** you can review and print PDF files across a broad range of hardware and operating systems.

Appendix E content	Filename	Description
F1	GWfield.pdf	This file contains qualified data from field measurements for Groundwater Field Parameters such as pH, specific conductance, temperature, etc…
F2	GW waterlevel.pdf	This file contains Groundwater Elevations from field measurements.
F3	GWconventionals.pdf	This file contains qualified data for Groundwater Conventional Parameters, such as pH, specific conductance, nitrate, chloride, etc…
F4	GWmetals.pdf	This file contains qualified data for Groundwater Dissolved Metal Parameters such as arsenic, iron, manganese, etc…
F5	GWrads.pdf	This file contains qualified data for Groundwater Radionuclide Parameters, such as radium 226, radium 228, etc…
F6	GWvolatiles.pdf	This file contains qualified data for Groundwater Volatile Organic Compound Parameters, such as dichloroethane, methylene chloride, vinyl chloride, total xylenes, etc…
F7	GWpestherb.pdf	This file contains qualified data for Groundwater Pesticide and Herbicide Parameters such as aroclor, endrin, 4,4'-DDT, toxaphene, etc…

KING COUNTY SOLID WASTE DIVISION
QUALIFIER INFORMATION
(Effective 4/1/2009)

QUAL	QUALIFIER DESCRIPTION
U	Undetected Analyte concentration <MDL Less than Method detection limit
T	Estimated, Less than Reporting Detection Limit but greater than Method detection limit
J	Reported value is an estimate
B	Contamination present in Blank
C	Confluent Growth
E	Estimated, outside expected accuracy
H	Exceeds holding time
R	Data Rejected
S	Sample handling errors
X	Too numerous to count
D	Dilution
P	PASS Qualitative result acceptable
F	FAIL Qualitative result is not acceptable
G	Greater than
L	Less than
